Syntax Reference

What is syntax?

In coding, **syntax** is the set of rules that describe the combination and sequence of symbols (including letters and numbers) that form a correctly structured program for a specific language like JavaScript.

Symbol	Name	Example 1	Example 2
/	Forward Slash	<body></body>	<pre></pre>
-	Dash	font-size: 20px;	\$("#two").css("background-color","10px");
11 11	Quotes	<pre></pre>	\$("#div1").hide();
1 1	Single Quotes	<pre></pre>	\$('#div1').hide();
< >	Angle Brackets	<head> </head>	html
{ }	Curly Brackets	<pre>p { color: blue; }</pre>	<pre>function wrongAnswer() { \$("#result").show(); }</pre>
[]	Square Brackets	<pre>var favColor = colors[1];</pre>	<pre>var colors = ["red", "blue", "yellow"];</pre>
()	Parentheses	\$("h1").hide();	wrongAnswer();
;	Semicolon	var word = "hello";	wrongAnswer();
:	Colon	<pre>#two { font-size: 20px; }</pre>	<pre>#two { width: 300px; }</pre>
•	Dot	<pre>\$(".yourclass").text("hi");</pre>	<pre>.yourClass { color: red; }</pre>
#	Hashtag	<pre>\$("#yourID").text("hi");</pre>	<pre>#yourID {color:red;}</pre>

Comments			
Comments allow you to include information for other coders and is ignored by the computer.			
These are comments in the code	Add a comment in HTML		
// One line of comments.	Add one line comment in JavaScript		
<pre>/* Type a long section in the comments */</pre>	Add a section of comments in JavaScript and CSS		

Mathematical Operators**			
Symbol	Definition Code Example		
+	Addition****	a + b;	
-	Subtraction	a - b;	
*	Multiplication	a * b;	
1	Division	a / b;	

^{**} Follow the order of operations rule **PEMDAS**: 1) Parentheses, 2) Exponents, 3) Multiply/Divide, 4) Add/Subtract ****Can *ALSO* be used to concatenate, or combine, strings, not just add numbers.

Comparison Operators			
Symbol	ymbol Definition Code Example		
<	Less than	if (number < 10)	
>	Greater than	else if (grade > 70)	
<=	Less than or equal to	if (points <= 100)	
>=	Greater than or equal to	else if (age >= 16)	
===	Equal to	if (username === "scripted1")	
!==	NOT equal to	else if (password !== "p@\$sw0rd")	

Logical Operators			
Symbol	ol Definition Code Example		
&&	And	if (number > 10 && number < 20)	
11	Or	if (grade > 65 passedRegents)	
!	Not	if (!(number < 10))	

HTML

Basic Structure of an HTML document (or webpage)

```
<!DOCTYPE html>
<html>
<head>
<title>My Page</title>
</head>
<body>
My first paragraph
</body>
</html>

My first paragraph

My first paragraph

My first paragraph
```

HTML Element			
is an individual component of a webpage			
Opening Tag	Content	Closing Tag	
1	↓	1	
< p>	This is a paragraph		

HTML Elements	Code Example	Output
paragraph	This is a paragraph.	This is a paragraph.
heading	<h1>Heading level 1</h1> <h6>Heading level 6</h6>	Heading level 1 Heading level 6
ordered list (w/ numbers)	<pre> George Washington John Adams </pre>	George Washington John Adams
div	<div>This is a div</div>	This is a div
input**	<input/>	

^{**}Self-closing: Does not have a closing tag.

	Nesting in HTML	
In coding, nesting is when you put one tag completely inside another tag's content. It allows you to organize your page's content into multiple levels.	<pre><div> <h1>Weekday</h1> Monday </div></pre>	On the left, the <h1> and tags are nested within the <div> tags because the <h1> and tags are completely within the opening <div> tag and the closing </div> tag.</h1></div></h1>

	HTML Attribute Syntax			
_	An attribute adds extra information to an HTML element. In HTML syntax, attributes are part of an HTML opening tag.			
Start w/ angle bracket	attribute	End w/ angle bracket		
1	↓	\		
< a	href="www.google.com"	>	Google it!	
	Opening Tag Content Closing Tag			

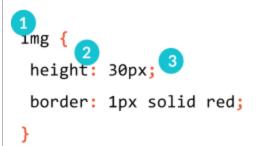

HTML elements w/ attributes	Code Example	Output
image **	<pre></pre>	
Link (anchor tag)	<pre>This is a link to Google</pre>	This is a link to Google
Adding id's*	<pre>text</pre>	text
Adding classes*	<h1 class="aClass">text</h1>	text
Input w/ placeholder**	<pre><input placeholder="type here"/></pre>	type here

^{*}You can add an id and/or class to any HTML element (, <a>, <1i>, <u1>, etc.) **Self-closing: Does not have a closing tag.

id vs. class		
Ids and classes are HTML attributes that you can add to HTML opening tags.		
id class		
 Each HTML element can only have one id. Each page can only have one HTML element with that id. In CSS and jQuery, the symbol that you use to select an id is a # (hashtag). 	 You can use the same class on multiple HTML elements. You can use more than one class on the same HTML element. In CSS and jQuery, the symbol that you use to select a class is a . (dot). 	

CSS

CSS Syntax

- 1. Selector: Identifies the parts of your page that will be affected by this CSS rule. You can select using the tag name, id, or class.
- 2. Property: The thing you want to change for the element(s) you've selected. Each property should be followed by a: (colon).
- 3. Value: What you want to set this property to. Each value should be followed by a; (semicolon).

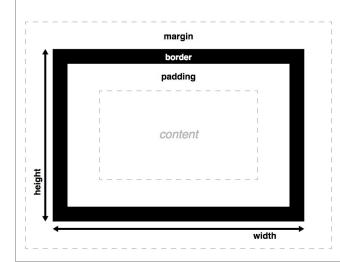

CSS Selectors				
Selector Symbol Code Example		Code Example	What it does	
tag	none	<pre>div { width:50px; }</pre>	Selects every div and gives them a width of 50 pixels. Other options for HTML elements (see above in HTML elements): p, body, h1, u1, li, img, etc.	
id	# hashtag	<pre>#myID{ color:blue; }</pre>	Selects the one HTML element with the id myID and changes the font color to blue.	
class	• period	<pre>.myClass{ text-align:right; }</pre>	Selects all the HTML element(s) with class myClass and changes the text so it's right-aligned.	

CSS Properties and Values			
Change	Code Examples	What it does	
text	<pre>font-family: "Comic Sans"; font-size: 12px; text-align: center; color: blue;</pre>	Changes the font to Comic Sans. Changes font size to 12 pixels. Aligns the text to the center. Changes the font color to blue.	
color	<pre>background-color: #000000; color: yellow;</pre>	Changes the background color to that hex code, which is black. Changes the font color to a specific shade of yellow.	
position	<pre>position: relative; position: absolute; position: fixed;</pre>	Positions the element relative to its parent element. Positions the element on the page based on defined offset values. Positions the element in same place, even as the page is scrolled.	
background	<pre>background-color: pink; background: url("www.ex.png");</pre>	Changes the background color to pink. Changes the background to an image w/ URL "www.ex.png"	
size	width: 50px; width: 50%; font-size: 20px;	Changes the width to 50 pixels. Changes the width to 50% of the screen, whatever the size. Changes the font-size to 20 pixels.	

CSS Layout

CSS Box Model

All HTML elements are shaped like boxes. Each box has a content area (text, image, link, etc.) and optional surrounding padding, border, and margin areas.

Box Model Properties

Content - (not a property) the HTML element i.e. paragraph, image, link, etc...

Padding - surrounds the content. (Example value: 10px)

Border - surrounds the padding. (Example value: 2px black) Think of it like an outline around a picture.

Margin - surrounds the border and buffers the content from other content. (Example value: 30px) Margin backgrounds are always transparent.

CSS Flexbox

Flexbox is a collection of CSS properties used to align and organize HTML elements on a web page.

```
outside {
    display: flex;
    flex-direction: column; 3
}
```

CSS

Use <div> tags to create the structure for flexbox styling. The two components are:

- 1. The parent element tells the elements that are nested within how they should behave (or appear) through CSS.
- 2. Child elements should be nested inside parent elements. You must have at least one child element, but can also have more than one. They can contain any HTML element, like <h1> or tags.
- 1. The selector should be the name of the parent element, in this case outside.
- 2. In the CSS, the parent element's display property MUST be set to the value flex. Use this entire line of code exactly the way it is.
- The flex-direction property specifies how child elements are organized... in this example, they are organized by column. The other possible value is row. Other flexbox properties include justify-content, with possible values of flex-start, flex-end, or center.

jQuery

jQuery Syntax

jQuery is a JavaScript library with different actions that make it easier to make your page interactive with JavaScript.

- 1. The \$ symbol lets you know that you are using jQuery, the JavaScript library.
- 2. The **selector** is exactly like a CSS selector. It selects or identifies the element on the page. You can use the name of an **HTML element** (, <h1>, <body>), **id** (#results, #div1) or **class** (.results, .div1).
- 3. The jQuery action() to be performed on the element. See more options below.
- 4. The **argument** tells more information about how to change the element. Sometimes, there is no argument, i.e. .show(), and sometimes, there are several arguments, i.e. .css().

Click Handler			
<pre>1 \$("#yourID").click(function(){ 2 //insert code here 3 \$("h1").hide(); 4 });</pre>	 When the user clicks the HTML element with an id yourId This is a comment. The computer does not read this as code. Use jQuery to hide every <h1> tag.</h1> End of the click handler. 		

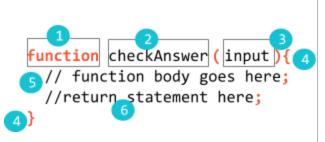

Action	Code Example	What it does	
Show an element. Hide an element.	<pre>\$(".yourClass").show(); \$("#yourID").hide();</pre>	Show all HTML elements w/ the class yourClass. Hide all HTML elements with the id yourID.	
Replaces the content of an HTML element.	\$("body").html("Hi!");	In the HTML, replace the content inside the <body> with Hi!.</body>	
Add/change the CSS, or style, of an element. (Change the property and/or value)	<pre>\$(".yourclass").css("color", "red");</pre>	Add/change the CSS property color to red for all HTML elements with a class of container.	
Add/change the text in an element.	<pre>\$("#yourID").text("You won!");</pre>	Add/change the text to "You won!" for the HTML element with the id results.	
Add/change an HTML attribute. (See page 4 for info about attributes.)	<pre>\$("img").attr("src", "http://pics.com/blah.jpg");</pre>	Add/change the HTML attribute src, or source, to that URL for all tags.	
Append (add) content to an element.	<pre>\$("div").append("Bye!");</pre>	Append, or add, the text "Bye!" to the end of the all the <div> tags.</div>	
Retrieve a value from an <input/>	<pre>var firstName = \$("input").val();</pre>	Retrieve a value from the input tag and store it in a variable named firstName.	

JavaScript

Function Syntax

A **function** is a set of instructions—the basic building block of a program.

A **function declaration** creates the set of instructions.

- The keyword <u>function</u> is <u>always</u> used to start a <u>function</u> declaration.
- 2. The name of this function is checkAnswer.
- 3. Some functions use parameters. The name of this parameter is input. You may also accept *multiple* parameters, separated by commas.
- 4. Curly brackets { } surround the body of the function.
- 5. The body of the function is the list of instructions, enclosed in the curly brackets.
- 6. The return statement stops the function and returns a value to the caller of the function. But, not every function has a return statement.

To use the list of instructions, you must make a function call.

- 2. To call the function, use the function name checkAnswer.
- 7. In a function call, you should pass an argument for every parameter in the function declaration. The parentheses () are always included, even if there isn't an argument. (see above).

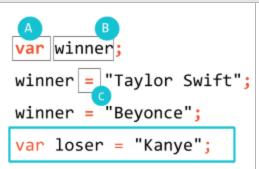

Function Example with Return Statement

```
1 function compoundWord(a,b) {
2    return a + b;
3 }
4 var word1 = compoundWord("can","not");
5
6 var word2 = compoundWord("fire","work");
```

- 1 Declare function compoundWord that takes 2 parameters.
- 2 Body: Return parameter a + parameter b.
- 3 End of function compoundWord.
- 4 Call function compoundWord, w/ arguments "can" & "not".
- 5 Assign it to the variable word1. The value is "cannot".
- 6 Call function compoundWord, with arguments "fire" and "work". The value of variable word2 is "firework.

Variable Syntax

Variables are containers for storing data values.

Parts:

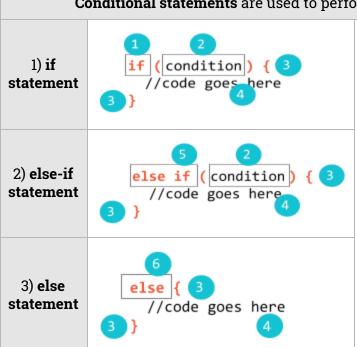

- A. The keyword var indicates declaring a variable, or creating a new variable.
- B. The variable name winner
- C. The equal = sign assigns a value.
- **Line 1: Declares a variable** and gives it a name winner.
- **Line 2: Assigns a value** to the variable winner.
- **Line 3: Re-assigns** a different value to the variable winner. The value of winner is no longer "Taylor Swift". It is now "Beyonce".
- Line 4: A shortcut! Declares a variable named loser and assigns it a value "Kanye" all in one line of code.

Value Types			
Number	Duh you know what a number is No quotation marks, may start with a + or -, may include a decimal.	<pre>var temperature = -1; var price = 5.99;</pre>	
String	Always inside single ('') or double ("") quotes. Can be an empty string "". Can include letters, spaces, symbols, numbers as long as it's in quotes.	<pre>var greeting = "Kevin is here!"; var space = ' '; var price = "\$5.99";</pre>	
Array	A list of multiple values separated by commas inside square brackets []	<pre>var oddNumbers = [1,3,5,7,9]; var airport = ["JFK", "LGA", "SFO"];</pre>	

	Example: Retrieve a value from an input			
1 2	<pre><input id="myID"/> <button id="yourID"> Go! </button></pre>	Creates an input field in HTML with an id myID. Creates a button that says Go! with an id yourID.		
1 2 3	<pre>\$("#yourID").click(function(){ var message = \$("#myID").val(); });</pre>	When the user clicks the HTML with an id your ID (which is the button), retrieve the value from the input field.		

Conditional Syntax

Conditional statements are used to perform different actions based on conditions.

} else {

6

\$("#buttonID').show();

Conditional Statements can be created using a combination of the three statements on the left.

- 1. The keyword if indicates that this is an if statement
- 2. The condition goes between the (); the result should be true or false. If you need multiple conditions, you will need an else-if statement.
- 3. Curly brackets indicate the body of the condition statement.
- 4. Body This is the code that executes if the condition is true. If the condition is false, then the code will NOT execute
- 5. The keyword else if indicates an else-if statement.
- 6. The keyword else indicates an else statement.

An **if statement** is required to create a conditional statement, while **else-if statements** and **else statements** may or may not be used. You can also use more than one **else-if statement**.

- 4 On also
- 4 Or else...
- 5 Show the HTML element with the id buttonID
- 6 End of conditional statement.

Array Syntax An **array** is a list-like way to store data. Index var classNames = ["English", "History". "Calculus"]; A. Declare a variable called classNames. B. An array is a list of values — they can be numbers, strings, or a combo. Square brackets start and end an array. C. Each array element, or individual item (i.e. "History") in the array, is separated by a comma. D. Arrays have properties that you can use, including length. Use the name of the array, in this case, classNames + var arrayLength = |classNames | .length to represent the length. The length of this array is 3, because there are 3 total elements in this array. The value of arrayLength is 3. E. To use a specific array element, use the array index. It (see above) represents the location of an array element and var favElement = classNames [0]; always begins with 0. The array index uses the name of the array + [the index surrounded by square brackets]. The value of favElement is "English".

For Loop Syntax

Loops repeat an action some # of times. A **for loop** repeats until a specified condition is false.

```
for (var count = 0; count < 4; count = count + 1){

//loop body goes here
}
```

- 1. Always begin the for loop with the keyword for.
- 2. The loop body goes between the curly brackets. This block of code executes when the three statements are true.

The Three Parts of a 'For" Loop:

- 3. The 1st statement, called the Initial Expression, declares a variable and value of where the loop starts. In this case, it declares a variable count and begins at 0.
- 4. The 2nd statement, called the **Condition**, tells the loop how many times to run. In this case, the loop will execute code as long as count is less than 4. In other words, the last time the loop will run is when count is 3.
- 5. The 3rd statement, called the **Increment Expression**, changes the variable value incrementally. A lot of times and in this case, the loop will increment, or increase, by 1. However, it could increment by 2 or 5 or 10, etc.

```
For Loop Example

1 for(var i=0; i=<5; i=i++){
2 $("#yourid").append(i);
3 }

1 Create a for loop that starts at 0, stops at 5, and increases by 1.
2 Append the value of variable i (0, 1, 2, 3, 4, 5) to element with id yourid.
3 Exit the loop when the variable i is no longer less than or equal to 5.
```

Appendix (in progress)

JavaScript

var num = 11; if (num < 5) { console.log("Less than 5"); } else if (num < 10) { console.log("Less than 10"); } else { console.log("Greater than 10"); } // Greater than 10</pre>

```
if (age > 16 && passedTest) {
    return "you can drive.";
} else {
    return "you can't drive.";
}
```

```
Complex Conditional Statement Example
                                                       Declare variable named age and assign it a value
var age = 35;
var status = "non-citizen";
                                                       of 35.
                                                    2
if (age >= 35 && status==="citizen"){
 $("#divID").text("You can run for president");
                                                    3
} else if (age >= 30 && status==="citizen"){
  $("#divID").text("You can run for senate");
else if (age >= 25 && status==="citizen"){
 $("#divID").text("You can run for the House");
} else {
 $("#div").text("You can't run for office!");
}
```
